

21st Annual GIS/CAMA Technologies Conference Chattanooga Convention Center

GIS/CAMA • Chattanooga, TN

IAAO

URISA

March 6-9, 2017

Continuing Education (CE) Credit

Recertification Credit forms for CE credit can be collected from the Registration Desk on Thursday.

Housekeeping

The conference proceedings will be available approximately 8 weeks after the conference.

Developing Natural Hazard Mitigation Plan with Parcel Data

Yu Zhou

Department of geography

Bowling Green State University

Bowling Green, OH 43403

yzhou@bgsu.edu

In Y2K, the Congress approved **Disaster Mitigation Act (DMA)**, commonly known as the 2000 Stafford Act amendments.

The Act encourages and rewards those county and state governments that develop and implement their community-specific mitigation plans.

As an incentive, the State of Ohio requires county governments to develop and submit mitigation plans in order to obtain disaster relief funds.

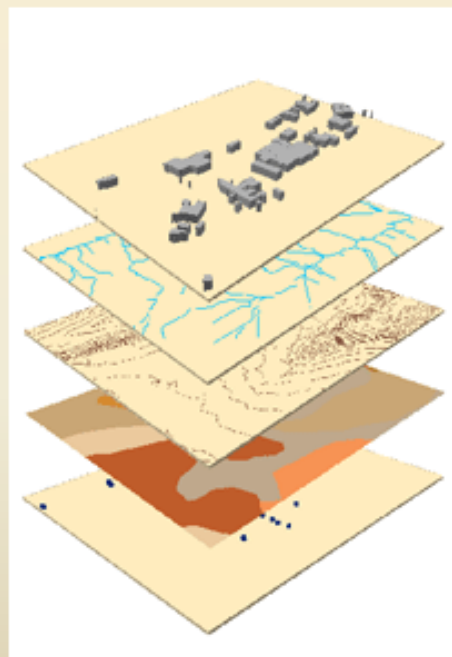

To produce a natural hazard mitigation plan, the first step, according to FEMA (the Federal Emergency Management Agency), is to:

- (1) identify the types of natural hazards that might affect the community; and
- (2) estimate the possible financial losses that might result from those hazards.

GIS (Geographic Information Systems) is a tool necessary to achieve the goals.

building
hydrology
topography
soil
borehole

Many county governments, however, do not have sufficient resources to produce their Natural Disaster Mitigation Plan.

Universities, with GIS resources and expertise, can help county governments producing natural disaster mitigation plans efficiently.

GIS was used to analyze natural hazards and estimate the possible financial losses from the hazards.

GIS analysis and the resulting maps became the centerpiece of each county's natural hazard mitigation plan.

Each county's mitigation was then submitted to the Ohio Emergency Management Agency (OEMA) and the Federal Emergency Management Agency (FEMA) for peer review.

Once a plan is approved by OEMA and FEMA, a certificate will be awarded to the county.

The county is then compliance with the federal Disaster Mitigation Act and qualified for natural disaster relieve fund.

The steps of using GIS to build a county-level mitigation plan including:

1. Collecting data

2. Performing GIS analysis

3. Producing maps

Data Collection

GIS data were first collected from each county's Auditor's office.

The data from county Auditor's office normally includes limited GIS layers (e.g., township, parcel) and aerial photos.

Parcel data is the most important layer in the planning process.

TIGER data, downloaded from www.esri.com, were also used as a supplement the county data.

Two major natural hazards were identified in the five counties: flood and tornado.

The flood maps, originally from FEMA, in shapefile format, were downloaded from the Ohio Department of Natural Resources' GIS warehouse

<http://www.dnr.state.oh.us/gismain/> .

The historic tornado data can be found at NOAA's (National Oceanic and Atmospheric Administration) website at <http://www.noaa.gov/> .

GIS Operations

GIS operations for the mitigation planning are relatively **simple** and **straightforward**.

First, all GIS layers need to be converted into the same coordinate system: Ohio State Plane Coordinate System (North Zone).

Ohio SPCS North Zone

Overlay is an essential operation in the GIS process.

Example:

find all parcels within 100-year flood zone

parcel

flood

parcels within
flood zone

Buffer function is also used in the process.

Example:

Buffer around the Class I dams

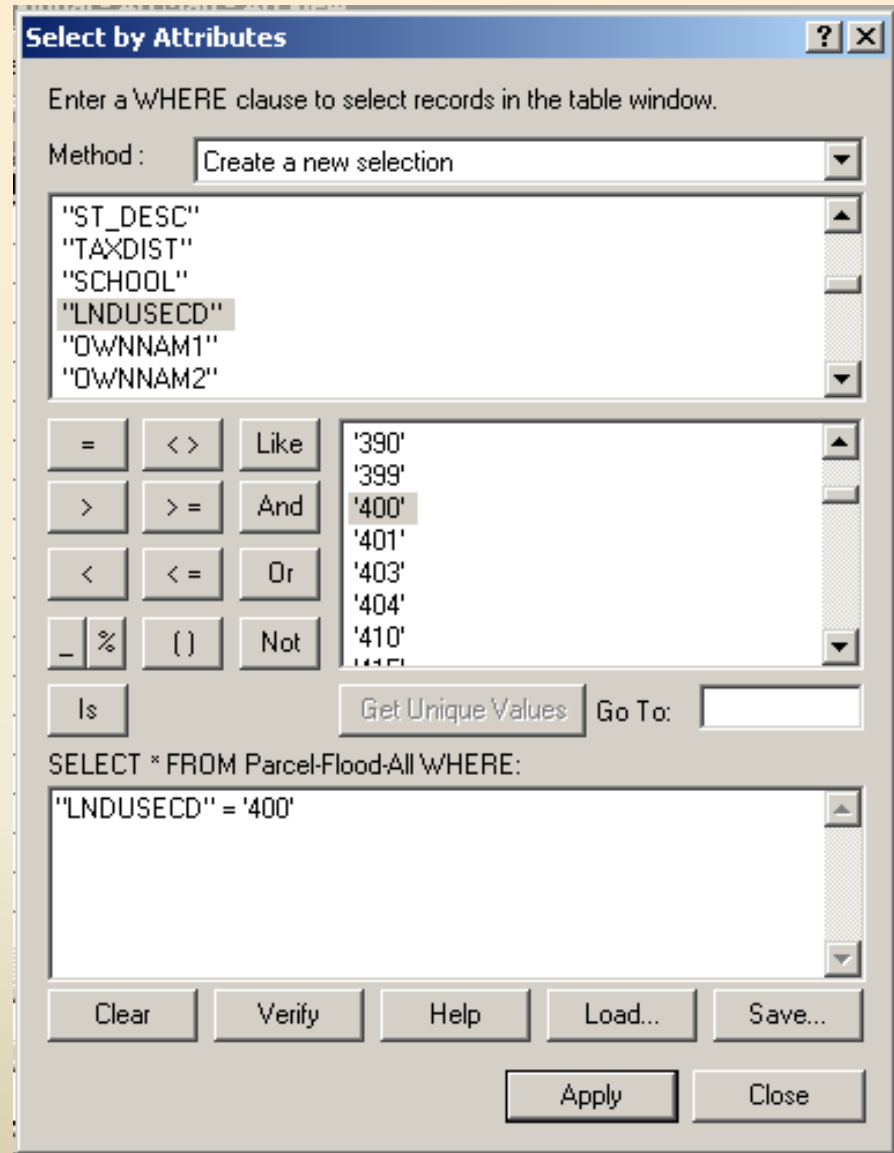

500/1000 feet vulnerability zones around Bowling Green water treatment reservoir

Attribute query is a fundamental function in estimating possible losses from a natural hazard.

Find all LULC code 400 in 100- year flood zone

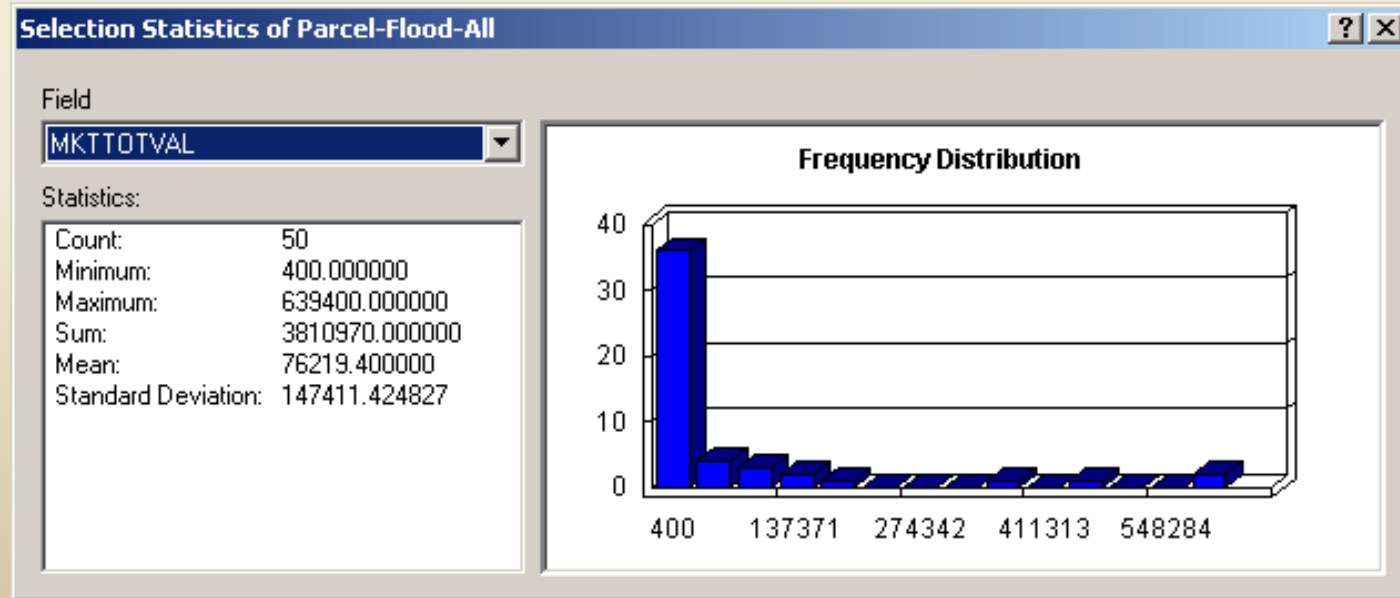

Estimate possible losses of LULC code 400 from a 100-year flood

Selected Attributes of Parcel-Flood-All

Parcels affected by 1953 Tornado Path

| Number of Parcels | | Value of Parcels | |
|-------------------|------------|------------------|--------------|
| Year: 1953 | Year: 2003 | Year: 1953 | Year: 2003 |
| 60 | 403 | \$1,500,000 | \$18,108,700 |

Problems

Making county-level natural hazard mitigation plan is simple and easy with GIS.

It can be done with basic GIS functions.

Some problems, however, have been experienced in the GIS processes.

Data Availability

Some counties, because of short GIS program history and lack of funding, provided only minimal or otherwise inadequate data.

Data Formats

One county only had parcel map of each individual township in AutoCAD format. These maps, without spatial references, had to be joined and converted to shapefiles.

Data Standardization

In many counties, the attribute tables could not be joined to the parcel map, simply because the parcel ID were not standardized.

Data Comparability

While some counties used USGS land use/land cover (LULC) classification system, some used unknown classification schemes.

One county's parcel layer does not have LULC field.

Data Accuracy (spatial)

Many parcels were not correctly digitized.
This was very evident in road-related polygons.

Data Accuracy (attribute)

In some counties, the parcel property values were not updated. The financial data generated from the queries, therefore, were not current.

Towards Better Parcel Database

The quality of county-level parcel database can be improved for the purpose of natural hazard mitigation planning.

Standardizing Database

County GIS database should be standardized.

Example:

parcel ID with same coding system

LULC with scheme (e.g., USGS)

Redesign GIS Database

Converting from shapefile to geodatabase.

Develop New Layers

It will be better if there is a building-based layer.

Utilize GIS Functionalities

In current mitigation planning, only a few basic GIS functions (e.g., overlay and query) have been used. The power of GIS spatial analysis has not been fully utilized.

Example: Evacuation plan with network functions should be included in the future for plan development.

GIS Modeling

Example:

use of risk modeling in natural hazard loss assessment.

GIS-Pro 2017

October 23-26, 2017
Jacksonville, Florida

The logo for GIS-Pro 2017 is set within a square frame. It features a stylized globe with a grid of latitude and longitude lines, rendered in a golden-brown color. The globe is positioned in the upper left quadrant of the frame. To its right, a city skyline is visible, with several skyscrapers in shades of blue and purple. The background of the entire logo area is a gradient of light blue and purple. The text 'GIS-Pro 2017' is written in a large, bold, teal-colored font across the middle of the frame. Below this, the dates 'October 23-26, 2017' and the location 'Jacksonville, Florida' are written in a smaller, white, sans-serif font.
